

Vladislav Goncharenko

Video recommendations team lead, Dzen

MSU & MIPT, fall 2023

In general, we want to recommend items (music/movie/article/product) to the user so that the user is happy (we work on long-term metrics)

A typical simplification of a user's happiness is whether a recommendation is liked at the moment.

Or even a bigger simplification —do you like the item as a whole or any item rating

for the user

The user himself can also be represented in different ways

- 1. As an unordered set of items that the user interacted with
- 2. As an unordered set of items with ratings
- 3. As a sequence of items with ratings
- 4. As a sequence of interactions taking into account the context

Revise

girafe ai

Basically, we will represent the user as an unordered set of items with ratings and try to predict the user's rating on other items

Evaluation matrix

Basically, we will represent the user as an unordered set of items with ratings and try to predict the user's rating on other items

A few formulas

$$\hat{\mathbf{r}}_{ui} = \frac{\sum_{j} s(i,j) (\mathbf{r}_{uj} - \mathbf{r}_{u})}{\sum_{j} |s(i,j)|} + \mathbf{r}_{u}$$

Explicit:
$$\operatorname{corr}(i,j) = \frac{\sum_{u} (r_{ui} - r_i)(r_{uj} - r_j)}{\sqrt{\sum_{u} (r_{ui} - r_i)^2 \sum_{u} (r_{uj} - r_j)^2}}$$
s(i,j)

Implicit:
$$J(A, B) = \frac{|A \cap B|}{|A \cup B|} = \frac{|A \cap B|}{|A| + |B| - |A \cap B|}$$

It strongly depends on the number of ratings per user and per item – the more, the more reliable the similarity.

This also leads to the possibility of pre-calculation: if there are a lot of estimates, then adding a pair of estimates will not change anything. Then you can update once in a while.

The similarities themselves can be used for other tasks (candidate generation, contextual recommendations).

A bit of linear algebra

girafe

Recall the main things about

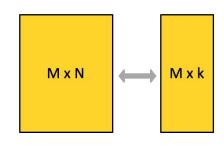

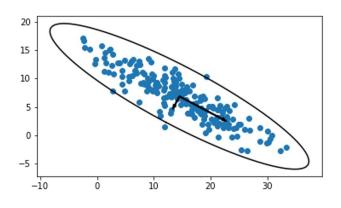

- PCA
- SVD
- Truncated SVD

PCA – staging

$$\sum_{i} dist(x_i, L_k) \to \min$$

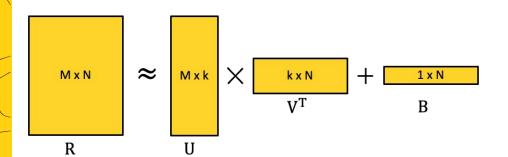

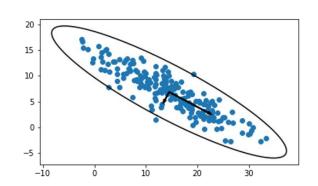

PCA – connection with matrix decompositions

$$r_{ij} = \bar{u_i}^T \bar{v_j} + b_i$$

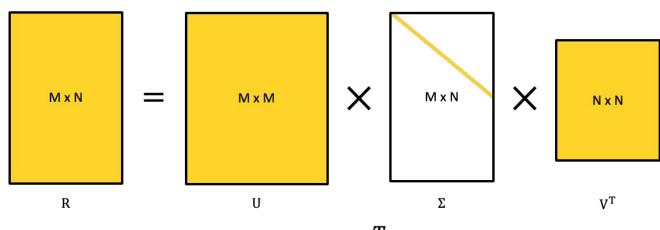

SVD

$$R = U\Sigma V^{T}$$

$$UU^{T} = U^{T}U = I_{M}$$

$$VV^{T} = V^{T}V = I_{N}$$

SVD compact

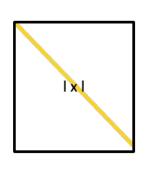

$$R = U\Sigma V^{T}$$

$$l = rank\{R\}$$

$$U^{T}U = V^{T}V = I_{l}$$

 V^{T}

 $r_{ij} = \overline{u_i}^T \Sigma \overline{v_j}$

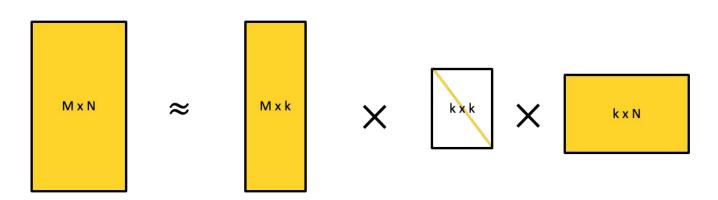

17

Truncated SVD

$$R \approx U \Sigma V^{T}$$

 $k \ll l = \text{rank}\{R\}$
 $U^{T}U = V^{T}V = I_{k}$

$$r_{ij} = \overline{u_i}^T \Sigma \overline{v_j}$$

Truncated SVD as optimization

$$R \approx U\Sigma V^{T} \qquad U\Sigma V^{T} = XY^{T}$$

$$U^{T}U = V^{T}V = I_{k} \qquad X^{T}X \neq I_{k}, Y^{T}Y \neq I_{k}$$

$$\min_{\substack{U,V,\Sigma\\U^TU=V^TV=I_k\\\sigma_{ij}=0,i\neq j}} \sum_{\forall i,j} (r_{ij} - u_i^T \Sigma v_j)^2 \iff$$

 $\sigma_{ii} > \sigma_{ij}, i < j$

$$\Rightarrow \qquad \min_{X,Y} \sum_{i \in I} (r_{ij} - x_i^T y_j)^2$$

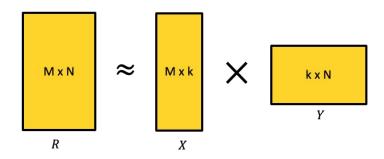

$$\min_{X,Y} \sum_{\forall i,j} \left(r_{ij} - x_i^T y_j \right)^2 + \lambda \sum_i ||x_i||^2 C_i + \lambda \sum_j ||y_j||^2 C_j$$

$$C_{i} = \frac{\left|\{j | r_{ij} > 0\}\right|^{\alpha} |\{i\}|}{\sum_{i} \left|\{j | r_{ij} > 0\}\right|^{\alpha}}$$

Truncated SVD as optimization

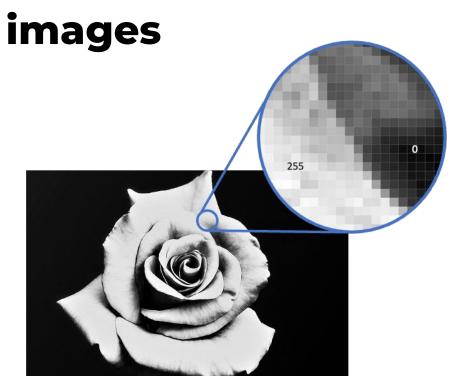

$$\min_{X,Y} \sum_{\forall i,j} (r_{ij} - x_i^T y_j)^2 + \lambda \sum_{i} ||x_i||^2 C_i + \lambda \sum_{j} ||y_j||^2 C_j$$

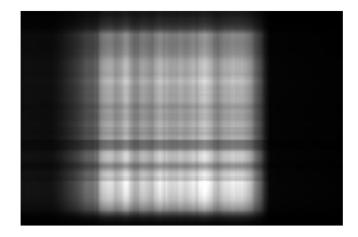

$$r_{i,j} = x_i^T y_j$$

Truncated SVD on the example of

400 x 600 image 240 000 values

400 x 1 / 1 x 1 / 1 x 600 matrices 1001 values

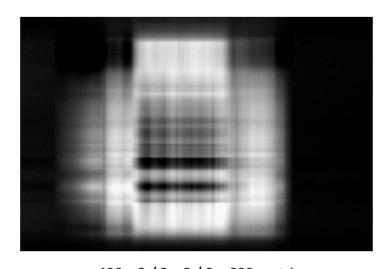

Truncated SVD on the example of images

400 x 600 image 240 000 values

400 x 2 / 2 x 2 / 2 x 600 matrices 2002 values

Truncated SVD on the example of images

400 x 600 image 240 000 values

item vector

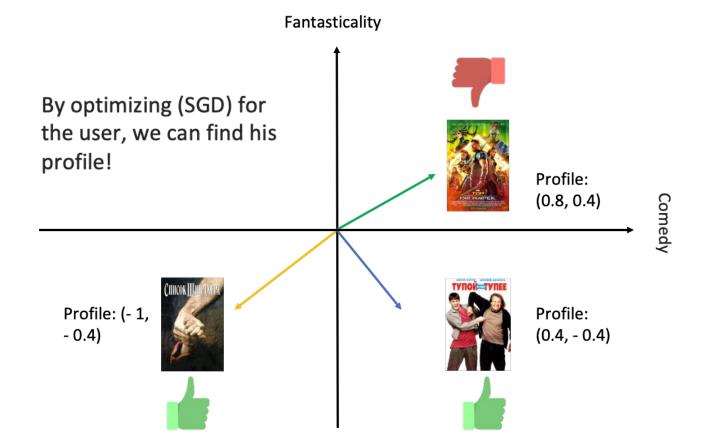

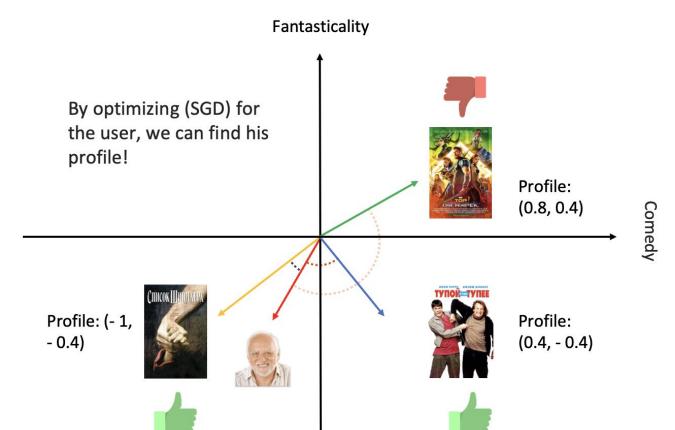

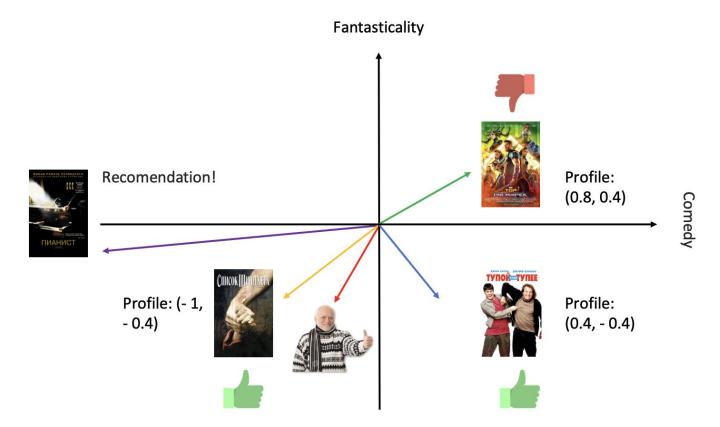

SVD Results

Matrix factorizations (MF) do not read the similarity of goods directly (as in CF).

MF attempts to describe users and products with a small set of characteristics that explain the ratings.

These characteristics may not be interpreted, at least the winds of items and users are determined with precision to the turn.

Unfortunately, SGD is difficult to parallelize.

Alternating Least Squares

ALS

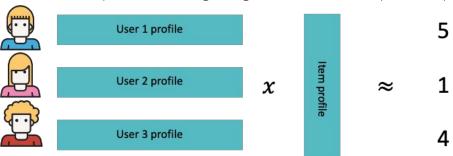

$$\min_{X,Y} \sum_{(i,j) \in R} (r_{ij} - x_i^T y_j)^2 + \lambda \sum_i ||x_i||^2 C_i + \lambda \sum_j ||y_j||^2 C_j$$

Initialize X and Y with random values.

In the loop:

- We fix the matrix X (users)
- Find the optimal matrix Y (solve the ridge regression for each product)

And vice versa

$$\underset{x_i}{\operatorname{argmin}} \sum_{(i,j) \in R} (r_{ij} - x_i^T y_j)^2 + \lambda \sum_i ||x_i||^2 C_i + \lambda \sum_j ||y_j||^2 C_j =$$

$$\underset{x_{i}}{\operatorname{argmin}} \sum_{(i,j) \in R} (r_{ij} - x_{i}^{T} y_{j})^{2} + \lambda \sum_{i} ||x_{i}||^{2} C_{i} + \lambda \sum_{j} ||y_{j}||^{2} C_{j} = \underset{x_{i}}{\operatorname{argmin}} \sum_{(i,j) \in R} r_{ij}^{2} - 2 \sum_{(i,j) \in R} r_{ij} x_{i}^{T} y_{j} + \sum_{(i,j) \in R} (x_{i}^{T} y_{j})^{2} + \lambda (x_{i}, x_{i}) C_{i} =$$

$$\underset{x_{i}}{\operatorname{argmin}} \sum_{(i,j) \in R} (r_{ij} - x_{i}^{T} y_{j})^{2} + \lambda \sum_{i} ||x_{i}||^{2} C_{i} + \lambda \sum_{j} ||y_{j}||^{2} C_{j} =$$

$$\underset{x_{i}}{\operatorname{argmin}} \sum_{(i,j) \in R} r_{ij}^{2} - 2 \sum_{(i,j) \in R} r_{ij} x_{i}^{T} y_{j} + \sum_{(i,j) \in R} (x_{i}^{T} y_{j})^{2} + \lambda (x_{i}, x_{i}) C_{i} =$$

$$\underset{x_{i}}{\operatorname{argmin}} -2x_{i}^{T} \sum_{(i,j) \in R} r_{ij} y_{j} + \sum_{(i,j) \in R} x_{i}^{T} y_{j} \cdot x_{i}^{T} y_{j} + \lambda (x_{i}, x_{i}) C_{i} =$$

ALS – step by x_i

ALS – step by x_i

$$\underset{x_{i}}{\operatorname{argmin}} \sum_{(i,j) \in R} (r_{ij} - x_{i}^{T} y_{j})^{2} + \lambda \sum_{i} ||x_{i}||^{2} C_{i} + \lambda \sum_{j} ||y_{j}||^{2} C_{j} = \\ \underset{x_{i}}{\operatorname{argmin}} \sum_{(i,j) \in R} r_{ij}^{2} - 2 \sum_{(i,j) \in R} r_{ij} x_{i}^{T} y_{j} + \sum_{(i,j) \in R} (x_{i}^{T} y_{j})^{2} + \lambda (x_{i}, x_{i}) C_{i} = \\ \underset{x_{i}}{\operatorname{argmin}} -2x_{i}^{T} \sum_{(i,j) \in R} r_{ij} y_{j} + \sum_{(i,j) \in R} x_{i}^{T} y_{j} \cdot x_{i}^{T} y_{j} + \lambda (x_{i}, x_{i}) C_{i} = \\ \underset{x_{i}}{\operatorname{argmin}} -2x_{i}^{T} \sum_{(i,j) \in R} r_{ij} y_{j} + \sum_{(i,j) \in R} x_{i}^{T} y_{j} \cdot y_{j}^{T} x_{i} + \lambda C_{i} x_{i}^{T} x_{i} = \\ \underset{x_{i}}{\operatorname{argmin}} -2x_{i}^{T} \left(\sum_{(i,j) \in R} r_{ij} y_{j} \right) + x_{i}^{T} \left(\sum_{(i,j) \in R} y_{j} y_{j}^{T} + \lambda C_{i} \right) x_{i} = \\ \underset{x_{i}}{\operatorname{argmin}} -2x_{i}^{T} B_{i} + x_{i}^{T} A_{i} x_{i} = A_{i}^{-1} B_{i}$$

$$\left(\sum_{\forall j | p_{ij} = 0} c_{ij} y_{j} \cdot y_{j}^{T} + \sum_{\forall j | p_{ij} \neq 0} c_{ij} y_{j} y_{j}^{T} + \lambda C_{i} I \right)^{-1} \left(\sum_{\forall j | p_{ij} \neq 0} c_{ij} p_{ij} y_{j} \right) =$$

$$\left(\sum_{\forall j} y_{j} \cdot y_{j}^{T} - \sum_{\forall j | p_{ij} \neq 0} y_{j} \cdot y_{j}^{T} + \sum_{\forall j | p_{ij} \neq 0} c_{ij} y_{j} y_{j}^{T} + \lambda C_{i} I \right)^{-1} \left(\sum_{\forall j | p_{ij} \neq 0} c_{ij} p_{ij} y_{j} \right) =$$

$$\left(Y^{T}Y + \lambda C_{i}I + \sum_{\forall j | p_{ij} \neq 0} (c_{ij} - 1) y_{j} y_{j}^{T} \right)^{-1} \left(\sum_{\forall j | p_{ij} \neq 0} c_{ij} p_{ij} y_{j} \right)$$

IALS – generalizations

The target p_{ij} can be not only 1 where there is a signal (we leave the implicit one equal to 0).

In confidence c_{ij} it is not necessary to use 1 as the default, any peer-to-peer matrix.three times.

The model can be slightly complicated by analogy with PCA:

$$r_{ij} \approx x_i y_j$$
 \longrightarrow $r_{ij} \approx x_i y_j + b_i + b_j + \mu$

You can combine several types of assessments with each other.

Other generalizations

ALS

$$r_{ij} \approx x_i y_j + b_i + b_j + \mu$$

$$r_{ij} \approx \left(x_i + \frac{1}{\sqrt{|\{s|p_{is} \neq 0\}|}} \sum_{\forall s|p_{is} \neq 0} \widehat{y_s}\right) y_j + b_i + b_j + \mu$$

$$r_{ij}(t) \approx \left(x_i(t) + \frac{1}{\sqrt{|\{s|p_{is} \neq 0\}|}} \sum_{\forall s|p_{is} \neq 0} \widehat{y_s}\right) y_j + b_i(t) + b_j(t) + \mu$$

Other generalizations (at the next lecture)
